

OSI Model – Data Units Concept Map

How Transformation of Data Units Supports Transmission

- **Segmentation** breaks large data into manageable pieces for end-to-end communication.
- **Packetization** adds logical addressing to enable routing across multiple networks.
- **Framing** adds physical addressing and error control for reliable node-to-node delivery.
- **Bit Conversion** converts frames into raw bits for actual transmission over the medium.
- At the receiver, the process is reversed (decapsulation) to reconstruct the original data.

Thus, transformation of data units at each layer ensures reliable, efficient and secure delivery of data from the source application to the destination application.
